AB The present invention relates to organic electroluminescent compds. represented by formula I, where Ar1 is a bond or fluorene derivative, Ar2 is fluorene or fluorene derivative, A and B are a bond, aryl group, Ar3-6 can be the same as Ar1-2, A and B, or halogen. The electroluminescent device is comprised of the compds. in an electroluminescent layer. The electroluminescent compound according to the invention has good luminous efficiency and excellent lifetime of the material, so that an OLED device having very good operation lifetime can be prepared

I

AB The invention relates to conjugated polymers and dendrimers containing styryl-triarylamine structural moieties of the general formula I, to their use in electronic components, especially in polymer organic LEDs, to monomers for producing the same, and to components and LEDs containing the polymers and dendrimers. In the general formula, each numbered Ar group is chosen independently from Ar groups having different nos. as a monocyclic or polycyclic aryl or heteroaryl, which is optionally substituted once or more by R1 (in Ar1 only), R2 (in Ar2 only), R3 (in Ar3 only), or R4 (in Ar4 only). In the general formula, every instance of Y is independently chosen to represent H, F, Cl, or a C1-C40 carbon or hydrocarbon group, whereby either two Y groups or a Y group and a neighboring R1, R4, Ar1, or Ar4 group may form as combined an aliphatic or aromatic, monocyclic or polycyclic ring system. In the general formula, R1, R2, R3, and R4 are independently chosen as H, F, Cl, OH, CN, N(R)2, Si(R)3, B(R)2, or as a C1-C40 carbon or hydrocarbon group, such that two or more of groups R1-4 can be combined to form an aliphatic or an aromatic, monocyclic or polycyclic ring system; and R1, R2, and R3 can also represent a covalent bond in the polymer or dendrimer. In the general formula, all occurrences of R independently represent H or a C1-C22 straight-chain, branched or cyclic alkyl, in which one or more neighboring CH2-groups are optionally substituted by C(R0)=C(R0), C-C, -N(R0), -Si(R0)2, O, S, CO, COO, OCO, OCOO, SCO, COS such that no two O or S atoms are directly bonded to each other. In the general formula, every instance of R0 independently represents H or a C1-C20 aliphatic or aromatic hydrocarbon. In the general formula, a is 1, 2, or 3; b is 1, 2, or 3; and c is 0 or 1.

AB The synthesis and photophys., electrochem., and spectroelectrochem. characterization of a novel donor-acceptor (D-A) bichromophore system composed of two D-A segments linking through a spiro center are reported. The electron-donating (D) moieties are triphenylamine (TPA) groups, whereas the electron-withdrawing (A) moieties are cyano groups. The particular "spiro" configuration that perpendicularly bonds the D-A chromophores by a tetrahedral carbon, impedes orbital interactions

between the branches. Thus, the two TPA substituents act independently, rendering an efficient electropolymm. process feasible. The polymer film obtained showed reversible electrochem. oxidation accompanied by strong color changes with high coloration efficiency and contrast ratio, which can be switched by potential modulation. The remarkable electrochromic behavior of the film is clearly interpreted on the basis of spectroelectrochem. studies. A plausible polymerization mechanism involved with the TPA dimerization reaction is proposed for the electropolymm. process.

ED Entered STN: 09 Mar 2006
AB High-efficiency polymer light-emitting diodes were fabricated by inserting a layer of nonionic neutral surfactant between the electroluminescent (EL) layer and the high-work-function Al cathode via spin coating. Both the poly(ethylene glycol)- and poly(propylene glycol)-based surfactants as well as their copolymers can all demonstrate similar performance enhancement. Device performances comparable to or even better than those of the control devices using Ca as the cathode were achieved for both poly(p-phenylene)-based and polyfluorene-based conjugated polymers with orange-red, green, and blue emission colors. It is possible that when both surfactant and Al are used as the cathode, the abundant hole injection through a hole-transporting layer and hole pile-up at the inner side of the EL/surfactant interface might cause an effective elec. field to induce the realignment of the dipole moment of those polar surfactant mols., thus lowering the barrier for electron injection. The coordination between the Al and O atoms on the surfactant might cause n-type doping in the areas near surfactant in the EL polymer layer that causes the enhancement of electron injection.

AB We have synthesized a novel polyfluorene copolymer, polyfluorene-bis[4-(diphenylamino)styryl]fluorene (PF-DPAS) by orthogonally attaching an amino-substituted distyrylarylene dye, bis[4-(diphenylamino)styryl]fluorene, onto the C9 position of a fluorene unit. We have investigated this polymer's thermal properties, electronic properties (viz., absorption and photoluminescence), and electrochem. behavior. Photoluminescence studies indicate that color tuning can be achieved through efficient Foerster energy transfer from the higher-energy polyfluorene backbone to the lower-energy pendent DPAS units. We have fabricated light-emitting diodes with the structure indium tin oxide (ITO)/poly(3,4-ethylenedioxythiophene) (PEDOT)/ emitting layer/1,3,5-tris(N-phenylbenzimidazol-2-yl)benzene (TPBI)/Mg:Ag. The devices, based on blends of PF-DPAS in. polyfluorene-triphenylamine- oxadiazole (PF-TPA-OXD), exhibit significant improvements in device performance relative to that of the pure PF-TPA-OXD device; we attributed this improvement to both a red-shift of the electroluminescence (EL) spectra and an enhancement in quantum efficiency. At a blend ratio of 1:20, the EL spectrum is voltage-independent and stable, and exhibits the characteristic emission of a DPAS moiety: a peak at 461 nm and Commission Internationale de l'Eclairage (CIE) coordinates of (0.15, 0.18). The maximum external quantum efficiency is 2.08 % (2.87 cd A-1) at a bias of 9 V (86.1 mA cm-2) with a brightness of 2467 cd m-2; the maximum brightness (6916 cd m-2) occurred at an applied voltage of 13 V and a c.d. of 361 mA cm-2.

AB Pure 2,2'-dibromo-9,9'-spirobifluorene (I) was synthesized by a method that did not involve troublesome dibromination of 9,9'-spirobifluorene or Sandmeyer reaction of 2,2'-diamino-9,9'-spirobifluorene. Starting from 4-Me3SiC6H4B(OH)2, I was prepared by Suzuki cross-coupling with 1,2-C6H4Br2, subsequent lithiation and condensation with (MeO)2CO, further bromodesilation, and finally spirocyclization by classical Clark and Gomberg method. A series of donor-acceptor orthogonally substituted 9,9'-spirobifluorene was subsequently prepared showing rich variation of fluorescence in solution and in solid state. Compound I was studied by x-ray structural anal. [monoclinic, space group P2(1)/c, a 14.5655(5), b 16.5819(5), c 7.9981(2) Å, β 93.4850(10)°, V 1928.16(10) Å3, Z 4].

AB Rare red-fluorescent fluorene derivs. were designed and synthesized. The long-wavelength red fluorescence is achieved by incorporating a di(4-tolyl)amino or diphenylamino electron donor and a dicyanovinyl electron acceptor. The single-crystal x-ray structures of the di(4-tolyl)amino (pTSPDCV) and diphenylamino (PhSPDCV) compds. indicate only weak non-π van der Waals contacts in addition to long-distance dipole-dipole interactions of the red-emitting fluorene mols. in the solid state. The aggregation of the dipolar fluorene is largely suppressed by introducing bulky 9,9-substituents (spiro-fused bifluorene) as well as a nonplanar di(4-tolyl)amino or diphenylamino group. In the solid state, these fluorene derivs. all show red fluorescence that is much brighter than with the red dopants Nile Red and DCM (4-(dicyanomethylene)-2-methyl-6-[4-(dimethylaminostyryl)-4H- pyran]). The unique photophys. properties of red-emitting fluorene derivs. differ from other known red dopants and facilitate the fabrication of nondoped red organic light-emitting diodes (OLEDs). Authentic red (CIE, x = 0.65, yr = 0.35) electroluminescence with a brightness of >12000 cd m-2 (greater than 600 cd m-2 at 20 mA cm-2) and a remarkable external quantum efficiency ≤3.6% were observed for the red-emitting OLEDs with pTSPDCV or PhSPDCV as the sole emitting host.

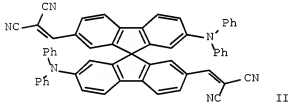
I



II

AB Crystal red fluorophores based on donor-acceptor substituted spirofluorene, i.e., I show strong fluorescence in solution (Φf.apprx.70%) as well as in solid state (Φf > 30%). Non-doped red OLEDs fabricated with I exhibit authentic red (CIE, x = 0.65, yr = 0.35) electroluminescence with brightness over 12,000 cd m-2 (or > 600 cd m-2 at 20 mA cm-2) and remarkable external quantum efficiency as high as 3.68%. On the other hand, the bis-substituted derivs. of spirofluorene II show relatively weak fluorescence both in solution (Φf < 20%) and in solid state (Φf < 10%). Although saturated red electroluminescence (CIE, x = 0.65, yr = 0.34) is also observed, non-doped red OLED containing II performs much worse than I OLEDs. Both PhSPDCV and BisPhSPDCV are not amorphous forming loosely packed crystal materials in solid state with no intimate π-π interaction.

AB Several different series of conjugated oligomers bearing various π-centers such as dithienothiophene (DTT), fluorene and terthiophene moieties, attaching electron donor and/or electron acceptor units through conjugation were synthesized and assessed for their nonlinear optical, 2-photon absorption and redox properties. Discussion is made on the property modulation role of the π-centers, particularly by DTT oligothiophene, which displays a unique and efficient electronic mediation.

AB Conjugated oligomeric and polymeric chromophores were synthesized by Wittig reactions of PPh3CH2-terminated donor (D) and/or acceptor (A) moieties with a bifunctional π-center, CHO-π-CHO. Two-photon absorption (TPA) was observed in the conjugated mols. bearing D and A pairs. The role of the π-conjugated linker (π-center) of the chromophores (D-p -D, D-p -A and A-p -A) on TPA activity was studied. These compds. are highly fluorescent, particularly with D/D pair chromophores relative to D/A pair as indicated by the fluorescence quantum yield, due to competing charge transfer pathways for decay of the singlet excited state. The redox potential of π2- and π3-containing chromophores is very similar when compared with the same D/D or A/A pairs. The oxidation potential is relatively lower for the D/D pair systems while the reduction potential is lower for the A/A pair system. The oligomeric TPA chromophores based on dithienothiophene (DIT) as π-center and different D and/or A moieties displayed exceptionally large TPA cross-sections, especially for D/D pair compared to D/A counterpart. This situation was reversed when the π-center was replaced with 9,9-spirobifluorene; a large enhancement of the cross-section was observed for the A/A pair relative to D/D. This result contrasts with that of 9,9-diethylhexylfluorene-based polymer, suggesting that mol. TPA is determined by the π-center and, even more significantly, by electronic interactions between the π-center and individual D and/or A pairs.
